Project Submission Sheet

Student Name: Raghul Sureshbabu

Student ID: x23377755

Programme: Msc data analytics **Year:** I

Module: Business Intelligence & Business Analytics

Lecturer: Sean Heeney

Submission Due Date: 08/03/2025

Project Title: Strategic Cybersecurity Incident & Audit Management:A CRM-Driven Approach with Salesforce and Power BI Analytics

Word Count: 4955

I hereby certify that the information contained in this (my submission) is information pertaining to research I conducted for this project. All information other than my own contribution will be fully referenced and listed in the relevant bibliography section at the rear of the project.
ALL internet material must be referenced in the references section. Students are encouraged to use the Harvard Referencing Standard supplied by the Library. To use other author's written or electronic work is illegal (plagiarism) and may result in disciplinary action. Students may be required to undergo a viva (oral examination) if there is suspicion about the validity of their submitted work.

Signature: Raghul Sureshbabu

Date: 08/03/2025

PLEASE READ THE FOLLOWING INSTRUCTIONS:

1. Please attach a completed copy of this sheet to each project (including multiple copies).
2. Projects should be submitted to your Programme Coordinator.
3. **You must ensure that you retain a HARD COPY of ALL projects**, both for your own reference and in case a project is lost or mislaid. It is not sufficient to keep a copy on computer. Please do not bind projects or place in covers unless specifically requested.
4. You must ensure that all projects are submitted to your Programme Coordinator on or before the required submission date. **Late submissions will incur penalties.**
5. All projects must be submitted and passed in order to successfully complete the year. **Any project/assignment not submitted will be marked as a fail.**

Business Intelligence & Business Analytics

Strategic Cybersecurity Incident & Audit Management:A CRM-Driven Approach with Salesforce and Power BI Analytics

Your Name/Student Number	Course	Date
Raghul Sureshbabu	Msc data analytics	08/03/2025

This section is a supplement to the main assignment, to be used if AI was used in any capacity in the creation of your assignment; if you have queries about how to do this, please contact your lecturer. For an example of how to fill these sections out, please click here.

AI Acknowledgment

This section acknowledges the AI tools that were utilized in the process of completing this assignment.

Tool Name	Brief Description	Link to tool

Description of AI Usage

This section provides a more detailed description of how the AI tools were used in the assignment. It includes information about the prompts given to the AI tool, the responses received, and how these responses were utilized or modified in the assignment. **One table should be used for each tool used**.

[Insert Tool Name]	
[Insert Description of use]	
[Insert Sample prompt]	[Insert Sample response]

Evidence of AI Usage

This section includes evidence of significant prompts and responses used or generated through the AI tool. It should provide a clear understanding of the extent to which the AI tool was used in the assignment. Evidence may be attached via screenshots or text.

1. Background Information & Business Goals

The world is getting hyper-connected and hence the situation of protecting a digital infrastructure which is becoming much inevitable that the agencies providing cybersecurity consultations like **CyberSec** is necessary. CyberSec belongs to the competitive sector of the enterprise strategically mapped by service and with recognizable service based MNC corporate clients. CyberSec provides an end-to-end intensity of cybersecurity services ranging from threat response, system mitigation, formal security audits and strategic compliance monitoring.

Despite their domain expertise, our company however experiences a fragmentation in its working patterns, in the course of its operational workflows, stemming from:

- Siloed data entry practices
- Excel dependent Incident monitoring
- Informal audit records
- Lack of data transparency to clients and teams.

These inefficiencies facilitate the lack of appropriate response and resolution rate and even lack of transparency when it comes to the reporting of the audit results and general inability to generate action out of the incident data. The issue of scaling the quality of the service and the possibility of making the decisions in real-time remain persistent without a centralized system in place.

In this respect, the project proposes a CRM-BI integrated system using tools like:

- **Salesforce** – Managing client accounts, Incidents and Audits.
- **Power BI** – Generating visual dashboards on attack types, consultant workloads and risk metrics.

The dual platform approach will equip CyberSec to have centralization of information, traceability, audit preparation and client segmentation under Continuous Improvement Program (CIP) like Kaizen, Six Sigma. It is deployed with regards to the premises of being scalable, Iterative and Quality assurance protocols.

1.1 Exploratory Business Observations (EDA Overview)

A preliminary analysis of internal service histories at CyberSec demonstrates that there are some general patterns in the operations that highlights the urgency of transformation process. A significant portion of cybersecurity incidents seems to be logged across a limited set of clients and this might indicate a repeat engagement or recurring vulnerabilities. The duration to resolve the incidents is different with a lot of variations, which is a sign of inconsistencies in service response.

Audits have occasionally highlighted elevated risks among certain business quarters due to the delayed resolutions or misaligned documentation practices. Although the amount of service data is growing, The current arrangement lacks structured data entry and organized reporting, preventing the firm to utilize this information effectively. A unified platform would facilitate this flow in an integrated manner besides enabling real time monitoring and accountability of all the operational stakeholders.

1.2 Strategic Positioning – SWOT Analysis:

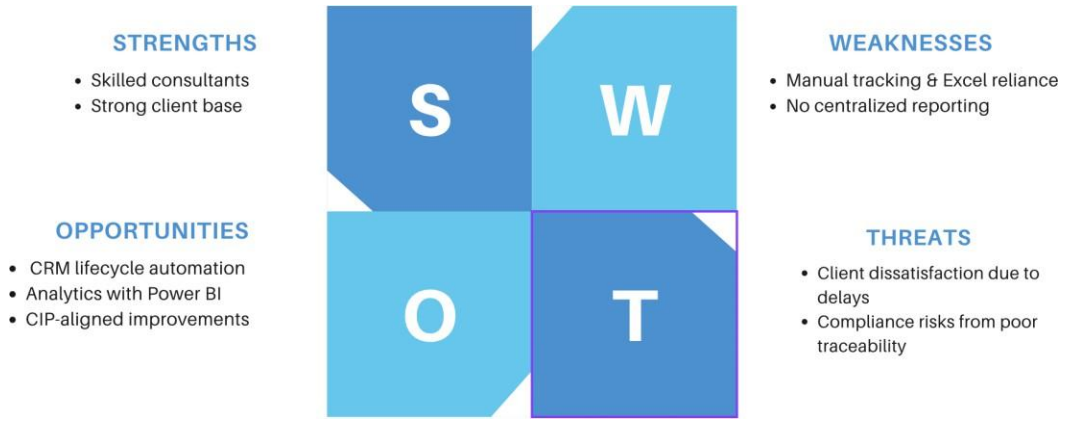

Figure 1.1 SWOT Analysis – CyberSec

CyberSec has a number of strengths such as a high skill level workforce of consultants and a long-standing relationship with the reputed organizations as clients. These assets are its core strengths in terms of credibility and market standing. Nonetheless, its excessive usage of manual tracking systems and unrelated documentation systems has exposed internal inefficiencies, which adversely affect expansion and accuracy.

There are opportunities in the area of the digital transformation of the CRM lifecycle automation of work, analytical tools, and visualization of data. This paves the way to an insight-based and agile style of working with the clients and their security. On the other hand, emerging risks like client dissatisfaction, failure to comply with audit and slow responsiveness time poses a factual threat to the continuity of the operation. A strong case can be made that CyberSec must act decisively to modernize itself and meet the rising of expectation from the enterprise clients.

2. System Architecture and Design

2.1 System Design

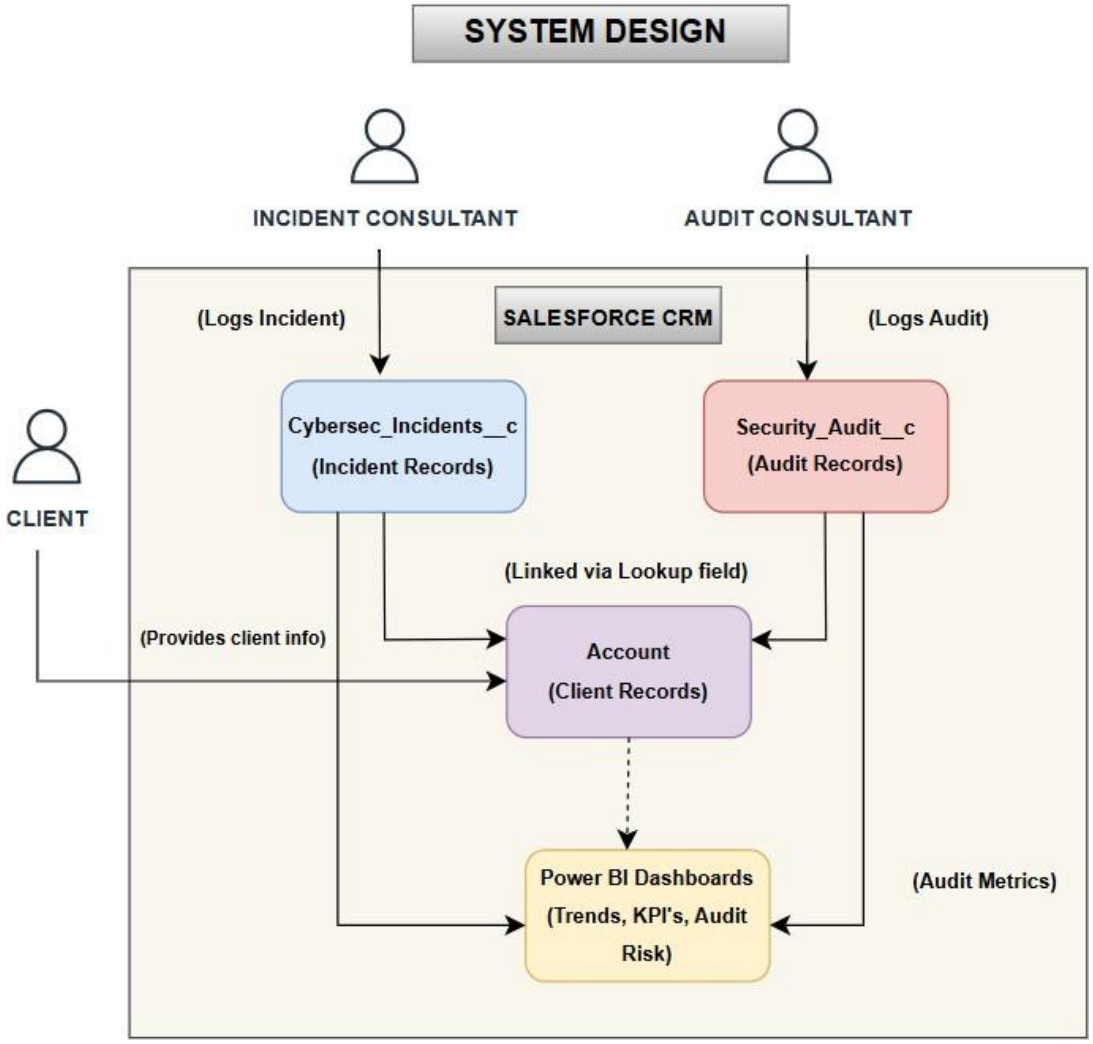

Figure 2.1 System Design for CyberSec

The operational inefficiencies of CyberSec are to be solved using a properly designed CRM-centric architecture. The way the system is designed with Salesforce as the backbone data source and Power BI as the visualization component simplifies the process of collecting, storing, and analysing cybersecurity incidents and audit digital records. The design also guarantees collaboration that is provided by clients, incident consultants and audit consultants them contributing to the various phases of security service lifecycle. Three mandatory custom objects, **Account** (to store metadata of enterprise clients HCL, TCS, Accenture, Infosys, and Cognizant), **CyberSec_Incidents__c** (to log and track cybersecurity incidents along with their severity, type, and resolution rates) and **Security_Audit__c** (to record the periodic audit clearances, risk value, and consultancy recommendation) are set up in the Salesforce CRM (Salesforce,2024). Lookup fields are used to connect these objects so that there is referential integrity and that it is very easy to do cross object reporting.

Power BI also serves as the outside business intelligence layer (Microsoft, 2024) where the data is pulled into the Salesforce environment for the sophisticated analysis. With this arrangement, real-time performance of incident resolutions, trends of attacks and classification of risk based on audit reports and consulting wise workload can be monitored. Through visualization of these parameters, applicable directions, making of decisions, emerging trends, as well as prioritizing interventions on data-driven priorities may be made. The dashboards are customized to give focused reports for operational leadership, quality assurance, and client involvement teams.

That means the clients are not direct users of the system, but their data is the epicentre of the CRM-BI system. These are the relation base of all incident and audit records which implies that all issues that are the result of operational activities are being allocated on the profile level as in relation to clients, on the level of service contact. Future improvements may involve salesforce experience cloud or automated report sharing where the clients will be able to access through secure portals, custom dashboards, audit summaries, or performance KPIs, hence maximize the transparency and client satisfaction and minimize manual communication work.

3. Database Design

A more solid and well-designed database structure forms the foundation of the CRM deployment of the CyberSec, and supporting incident response records and audit data at scales. The main data entities related to this design are **Client, CyberSec_Incidents** and **Security_Audit** which are represented in the form of Salesforce standard and custom objects. The **Entity Relationship Diagram (ERD)** brings out the way these entities relate to each other and the result is a nice and a normalized relationship model. Particularly, both

the Incident and Audit objects have a lookup relationship with the Client object, which creates one-to-many (1:M) integrity on the client accounts

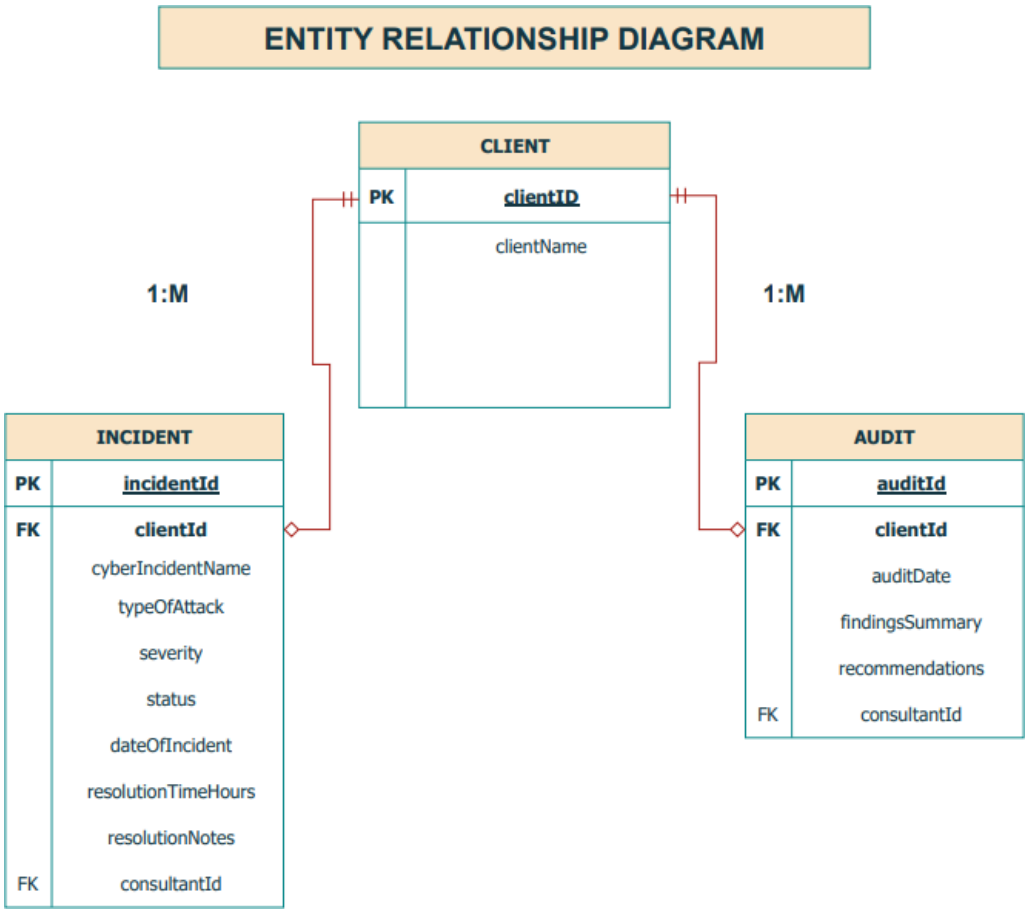

Figure 3.1: ERP Diagram - CyberSec

The above ERD captures the logical flow of data between these elements, wherein each of the incidents or audits will be listed specifically under the client to which it is applicable. Such a structure avoids data fragmentation, and the aggregation of analytical processes, and traceability among different organizational events. Also, the fact that fields like consultantId have been added can make the role-based responsibility and performance attribution possible. Although incident and audit consultants may be tracked using distinct identifiers, Salesforce provides the opportunity to be flexible in managing these roles by using field-level lookups, which will allow one to be adaptable in situations where marketing specializations differ.

Data Dictionary Table

TABLE NAME	FIELD NAME	DATA TYPE	DESCRIPTION
Client	clientId	INT (A.I, P.K)	Unique identifier for each client in the organization
	clientName	INT	Name of the organisation (e.g. HCL, TCS)
Incident	incidentId	INT (A.I, P.K)	Unique identifier for each cybersecurity incident
	clientId	INT (F.K)	Foreign Key referencing the client
	cyberIncidentName	VARCHAR	Name/Title of the incident
	typeOfAttack	VARCHAR	Type of cyberattack (e.g. DDOS, SQLi)
	severity	VARCHAR	Severity level of the incident (Low/Medium/High/Critical)
	status	VARCHAR	Current status (Open, Closed, Investigating, Resolved)
	dateOfIncident	DATE	Date of the incident
	resolutionTimeHours	FLOAT	Time taken to resolve the incident (Hours)
	resolutionNotes	TEXT	Documentation on the resolving process
	consultantId	INT (F.K)	Unique identifier of the consultant handling the incident
Audit	auditId	INT (A.I, P.K)	Unique identifier for the audit records
	clientId	INT (F.K)	Foreign Key referencing the client
	auditDate	DATE	Date of the audit
	findingsSummary	TEXT	Key observations and identified improvements

	recommendations	TEXT	Recommended actions to mitigate risks
	consultantId	INT (F.K)	Unique identifier of the consultant handling the audit

Table 3.1 Data Dictionary – System Design

The Data Dictionary that accompanies the ERD is more detailed elaborating the definition of key fields, type of data used, and the connections between the various objects consumed. It will have such field definitions as **typeOfAttack, severity, resolutionTimeHours, auditDate, and findingsSummary** which have been properly mapped to the various objects. Besides setting the record straight on schema design, this dictionary can also be analyzed academically and, with regard to BI-readiness, it can be suggested that the dictionary is reflective of Power Bi extraction and transformation logic. The ERD and the data dictionary combined depicts that the database layer is well-constructed, analytically comprehensive and strongly bonded to the CRM processes and dashboarding solutions.

4. Data & Pre-Processing

To create a realistic working environment with CyberSec CRM system, a complete dataset was created on the basis of Mockaroo (Mockaroo,2024), a powerful tool to generate synthetic data. This data was prepared carefully to match the relational schema and field requirements of Salesforce and will be readily imported into Salesforce, as well as offering maximum possibilities in terms of analytics because relationships are established correctly and data is properly prepared.

Custom fields have been set up in both **CyberSec_Incidents__c** and **Security_Audit__c** such as **Type of Attack (DDoS, SQLi, Phishing, etc.), Severity (Low, Medium, High, Critical).** The incidences have been scheduled between year **2024-2025** and the resolution notes synthesized to include curated cybersecurity action phrases to simulate actual consultant input. Fields like **Client_Name__c** were linked as a lookup field to Salesforce Accounts (e.g. HCL, Infosys, TCS) and the consultants were randomly assigned so that there would be variety in roles.

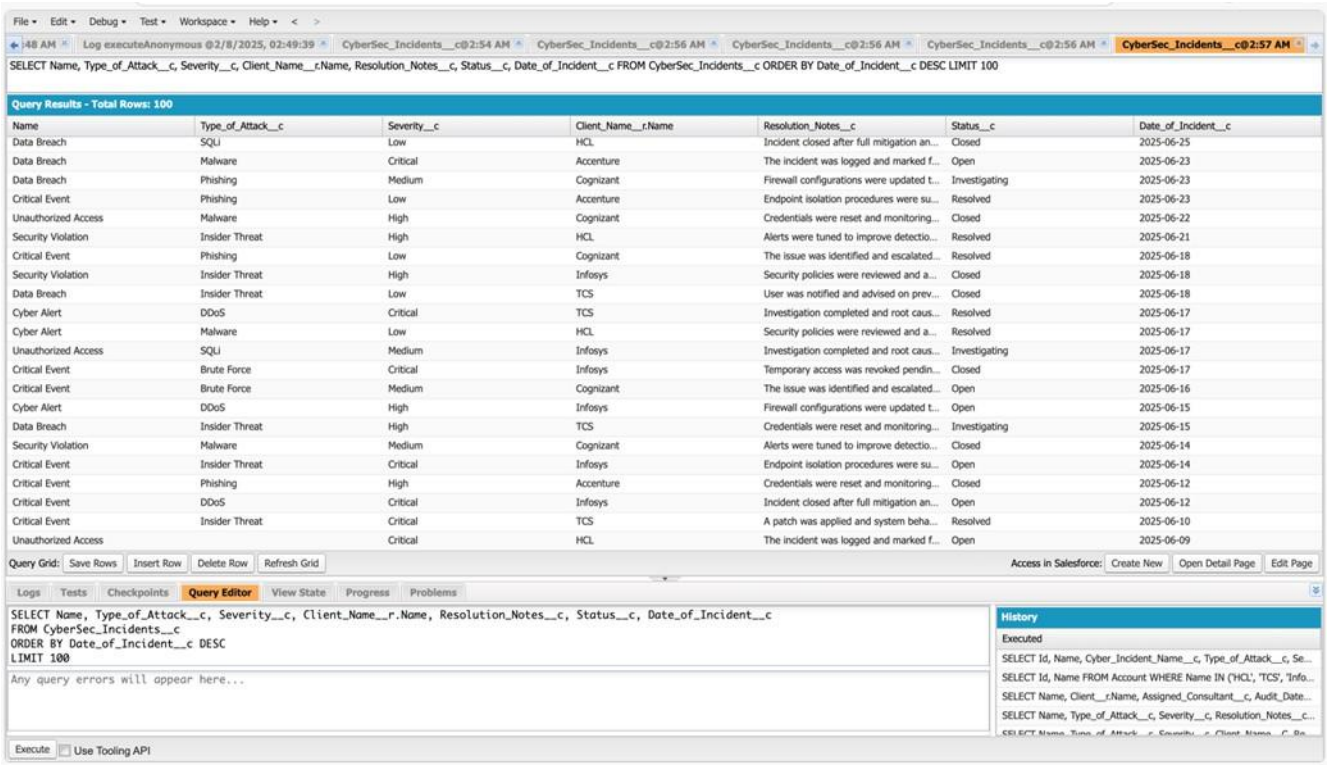

Figure 4.1 Data and Pre-Processing in Salesforce

Particular consideration was drawn during pre-processing on Salesforce limitation:

- The format of date is **YYYY-MM-DD** (ISO 8601)
- Matching on Picklist was strictly followed with Salesforce metadata
- Relationships that were defined as foreign key such as (client-id and consultant-id) were dynamically resolved within **Apex**
- Duplicates were found and eliminated by using **SOQL query**, where bulk insertions could not be performed because of dependency or mismatch of records, Apex scripts were implemented to do the insertion programmatically.

The combined strategy allowed generating more than **843** structured CyberSec Incident widgets and several audits in the actual client accounts. Validation was applied both by using **Data Loader** and **SOQL queries** which confirmed their proper mapping and population.

To prove that the basic preprocessing and incorporation of data into Salesforce CRM ecosystem was successful, a well-organized **SOQL** was performed in the **Developer Console**. The resulting result, which in the above picture have presented the **sample of 100 incident records** found within the **CyberSec_Incidents__c** object. The records are ordered according to the date of incident, and they prove that all the important fields are filled correctly. In particular, the presented columns contain the name of the

incident, the type of the attack, the level of the severity, the notes about the resolution, the status of the incident, and the date on which it happened. In addition, the **Client_Name__r** field is another way of ensuring that account lookups are performing as expected by resolving client names into human-readability. This reflects the integrity and structural soundness of the data and confirms its preparedness in being used in subsequent analytics in Salesforce dashboards and Power BI reports.

5. Conclusion:

The specification report describes a generalizable and extendable solution to the long-standing issues that CyberSec faces, which are incident and audit management. With the use of Salesforce as centralized CRM and PowerBI as a dynamic reporting system, the suggested system will provide superior traceability, real-time awareness and insider knowledge to all cybersecurity activities.
The database structure, mock data, and well-organized system framework are designed in such a way that they guarantee not only technical soundness but also that the intended business objectives are fulfilled. In addition, the ability to include the lookup relationships, structured audit, and incident traceability provides additional compliance posture and the ability of the organization to analyze risks.

This CRM-BI combined framework in general sets the foundation of continuous process improvement (CIP) that enables CyberSec to respond to the threats effectively to be audit ready and capable of strategic decision-making within its domestic customer base.

Team Contributions

Team Member	Specification Report	Implementation Report
Hariramakrrishnan Ramachandran	Mockdata creation in Mockaroo, Salesforce CRM design and documentation	Salesforce CRM setup, Salesforce Report creation and Report implementation
Raghul Sureshbabu	System and Database design, Dashboard analysis	Power BI dashboards, CRM-BI integration, workflow and Report implementation
Tamilventhan Paranthaman	Content structure, Assist in System design and CRM sections	Supported CRM and dashboards implementation and Final documentation review

Strategic Cybersecurity Incident & Audit Management: A CRM-Driven Approach with Salesforce and Power BI Analytics

IMPLEMENTATION REPORT

1. Development Process - Concept to Implementation

The CyberSec CRM-BI system development process started with a vision to transform the way that cybersecurity incidents and audits are managed by clients on the enterprise level digitally. In the first phase, the architecture was concerned with Salesforce as a CRM platform only. Two custom objects were made- **CyberSec_Incidents_c** and **Security_Audit_c** and the standard Account objects that comprised of client companies such as HCL, TCS, Infosys, and Accenture. These objects were well modelled with a use of a look up relationship so that they can handle the relational and scalable data. The field types were created to accurately recognize audit and incident modules to include areas as picklists, look-up reference, long text fields, and numeric measures.

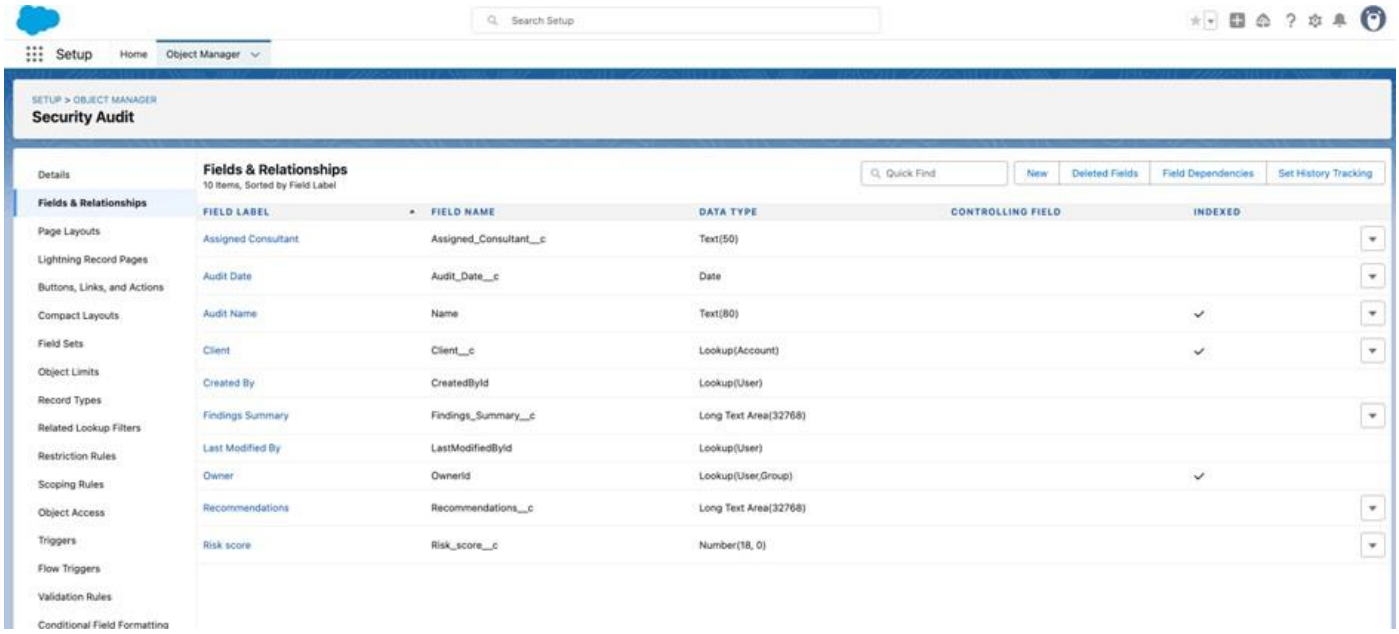

Figure 1.1: Object Manager in Salesforce showing field configurations for Security_Audit__c object

During the implementation process, some unknown complexities started emerging, most especially in the data uploading process and mapping of the records. The look ups of manual imports used to fail because of mismatched lookups, or invalid pick list values or improperly formatted dates. To address these bottlenecks,

the development team has provided Apex automation of inserting and updating batches of records. Client and consultant objects had to be pre-loaded in order to resolve foreign keys correctly. SOQL queries were used to perform real-time validations and data integrity of Salesforce via the Developer Console. This transition towards programmatic development became a large step toward the increased rigor and professionalism in the project.

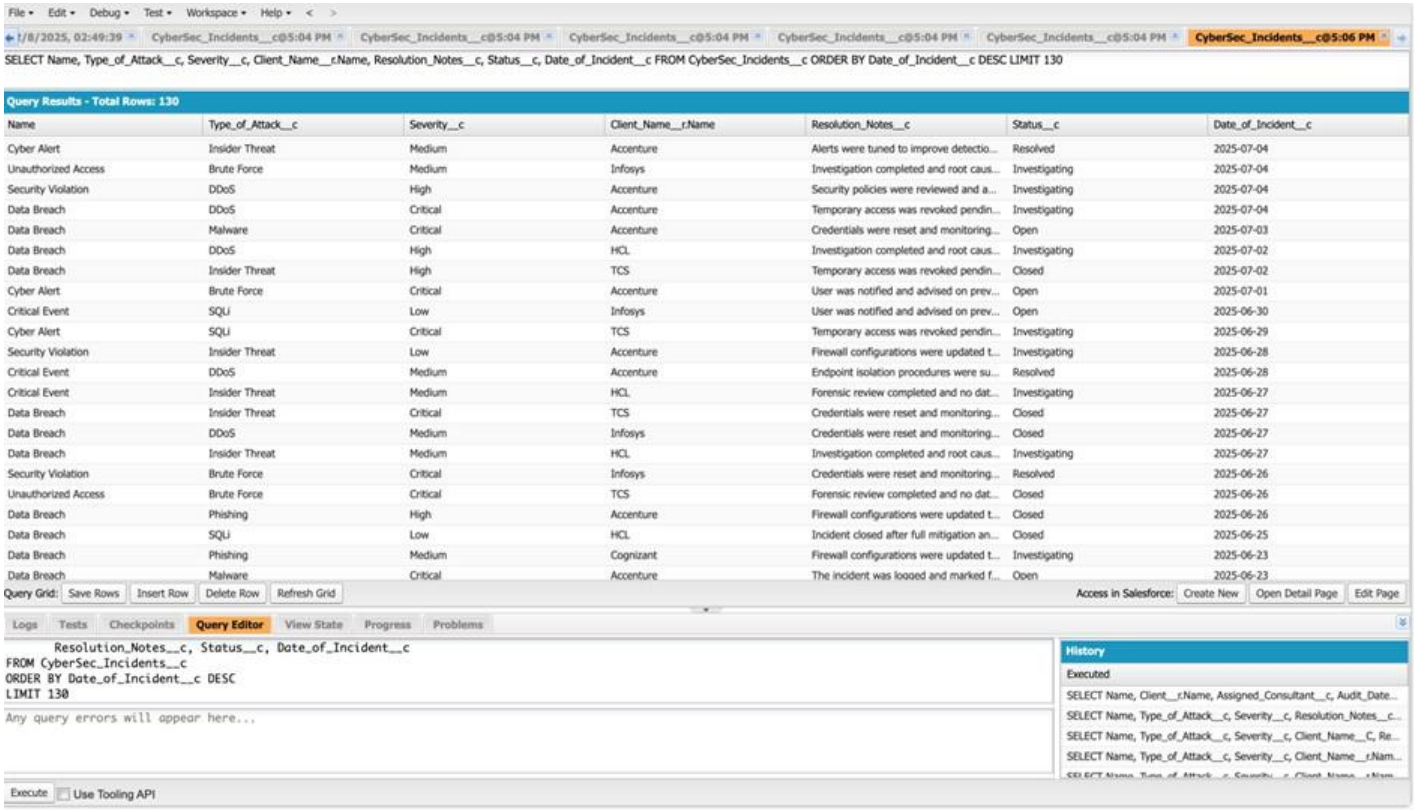

Figure 1.2 Developer Console displaying 130 rows of resolved CyberSec incident records using SOQL query

In order to provide a wider view of the analytical capabilities other than the built-in Salesforce reports, the project was expanded into integrating Power BI, so that it could support dynamic dashboards about indicator performance, attack patterns and consultant activities. This upgrade provided the project with an enterprise-ready analytics layer that had real-time refresh ability. The iterative process and the evolution on the tooling helped not only to enhance the system functionality but also to align it with the concepts of modern non-stop improvement.

Key Enhancements Introduced in Development

- **Automated Record Insertion via Apex**: The limitation of uploading only 10,000 records per CSV file was eliminated by bypassing the uploader and programmatically inserting both incidents and audit records with proper null values handled and proper references created through a valid look up.
- **Power BI Integration**: Expanded the analytical layer with visualizations of consultant performance and the KPIs concerning incident resolutions, and the trends of audit risks related to the clients.
- **SOQL-Based Data Validation**: Using a leveraged Salesforce Developer Console, queries ran which checked data integrity, found duplicates and ensured consistency with respect to key objects.
- **Picklist & Lookup Repairs:** Restored picklist settings and got rid of the inconsistencies between the client and consultant references to have smooth imports and consistency.

Table: Development Milestones & Tools Used

Phase	Description	Tools & Techniques
Object Setup	Designed custom fields, validation rules, and an incident and audit, as well as the customization of relationships	Salesforce Object Manager, Schema Builder
Data Population	Produced mock data and field level import resolves intakes	Mockaroo, Data Import Wizard, Field Mapping Utilities
Programmatic Insertion	Addressed mapped failure records through bulk Apex scripts conditional logic	Developer Console, Apex Code, DML Exception Handling
Report Integration	Tracking performance and risks with help of BI dynamic dashboard	Power BI Desktop, Salesforce Connector
Data Verification	Verified by successful imports and mappings of foreign keys carried out on SOQL queries	Salesforce Developer Console, Query Editor

Table 1.1 Development Milestones & Tools

2. Implementation Evidence: Objects, Field Logic, and Validation Controls

The CyberSec CRM solution was designed in Salesforce with declarative technology and low-code tools with the purpose of responding to enterprise-level data integrity and user access requirements. The entire architecture is based on the two custom objects, **CyberSec_Incidents_c**, which tracks incidents and **Security_Audit__c** to document the audits so the objects are custom to follow industry-standard cybersecurity processes. All objects have custom fields like **Severity__c**, **Status__c**, and, **Resolution_Notes_c** with picklists, text areas, and numeric inputs. Relationships were carefully designed through the use of look up fields with the Account object (clients) and the User object (consultants) to have traceable and normalized data. This design decision is based on how to reduce redundancy and enhance the referential integrity between objects.

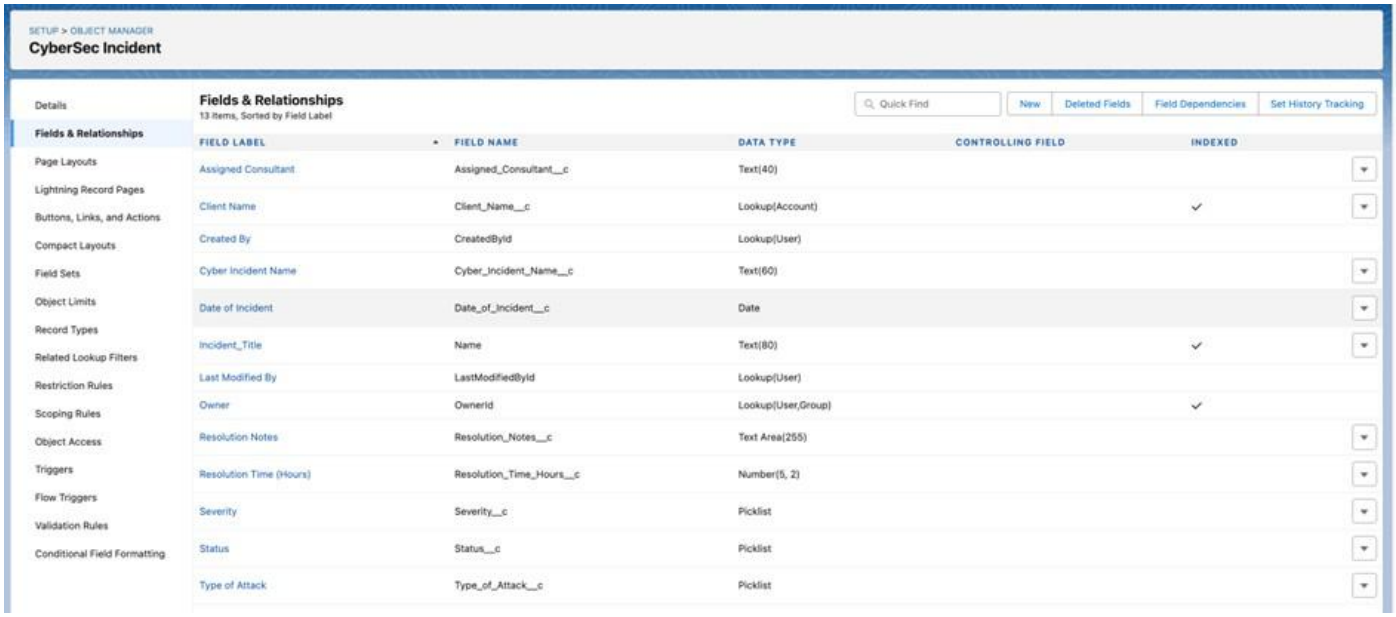

Figure 2.1: *Fields & Relationships tab for CyberSec_Incidents__c*

The above figure showcasing critical field types including Lookup (Account), Picklist (Status), Long Text Area (Resolution Notes), and custom numerical metrics.

The project leveraged field-level security, page layouts, and access roles in Salesforce to an extremely large extent in order to satisfy the data management aspect of the solution. Organization policies are enforced by field level validations (e.g. requiring field Resolution_Notes_c to be filled in when status_c field is Resolved). Conditioned page layouts were created to divide the access by the user roles (e.g. Consultant vs. Admin) and the data input was limited to meaningful combinations of record types and fields. Assigned_Consultant__c was also added as a lookup filter so that invalid or deactivated users could not be

chosen. Although they were not built with the use of Apex Triggers, the implementation of formula fields, data type limitations and validations maintained at page level ensured quality data entry and execution of processes.

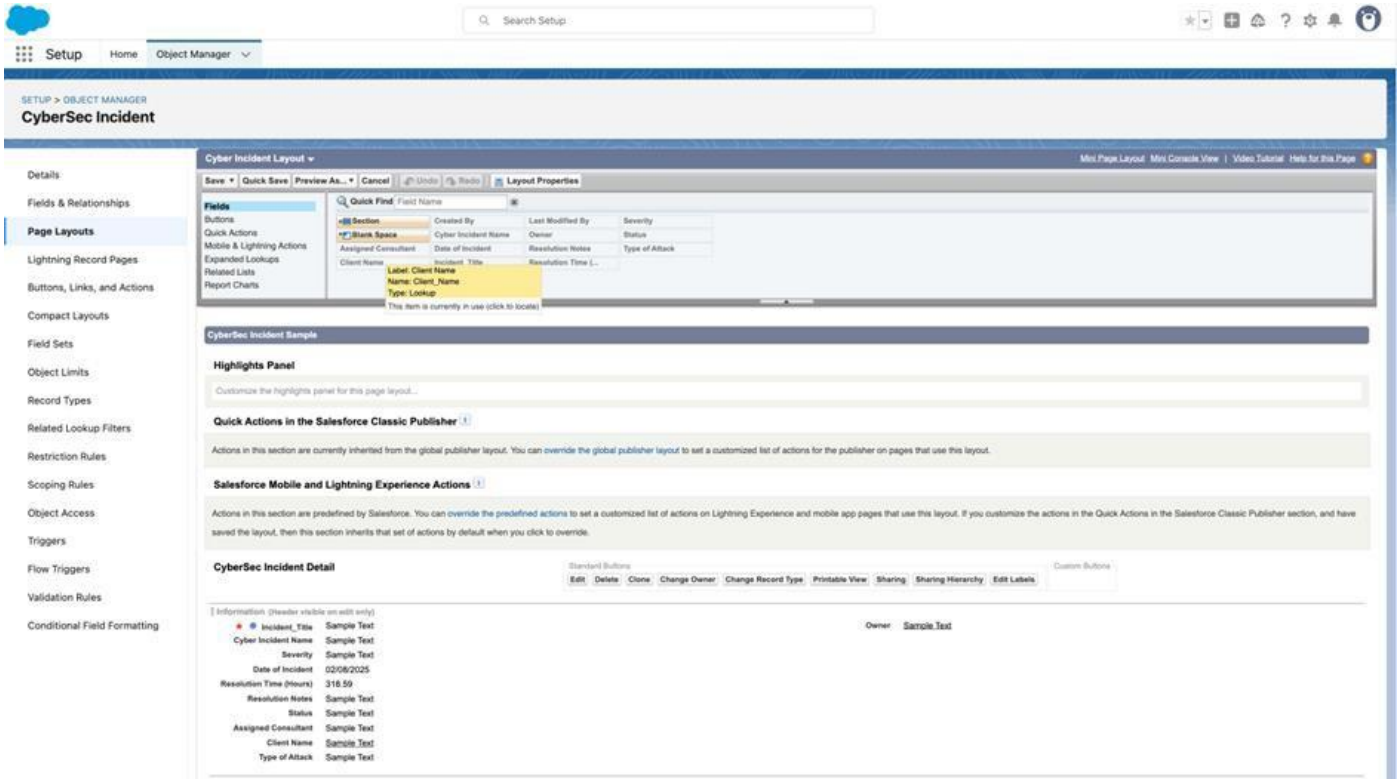

Figure 2.2 Page Layout of cyberSec Incidents in Salesforce

Additionally, the system controls were at the object level and data was not visible unless there were sharing settings built into sales a forced when a required access control lists. As such, consultants are only allowed to see and make changes to the records assigned to them, whereas admins got full access. No triggers were specifically created, but the use of rule-based controls out of the box was used to impose logical flow conditions, e.g., on restricting record closure without completion of the audit or without mandatory use of a severity tag. All these steps create a high-integrity, role-conscious CRM environment, which is ready to use with Power BI reporting and to be upscaled to enterprise.

Implementation Highlights:

- **Declarative Configuration Mastery**: All the important workflow and data governance rules were done using native features of Salesforce-there was no use of code-intensive triggers or flows.
- **Field-Level Precision:** All custom objects have only picklists, validation rules, and look-ip filters, which make the data clean, consistent and traceable.

- **Role Based Access Control:** Profiles and layouts have been customized so, only one type of consultant can access to it, and this enhances the security and has ease.

3. Reports & Dashboards

The CRM-BI solution developed in CyberSec involved the preparation of various dashboards and reports that allow engaging in real-time tracking, monitoring, and, study of cybersecurity events. The visual tools provide a simplified, real-time picture of the critical measurements, which inform all the stakeholders regarding the trends, the distribution of workload, and client performance without technical knowledge.

Figure 3.1 – Power BI: CyberSec Incidents Dashboard

This Power BI dashboard will provide the overall picture of incident-related operations in the organization. It contains the total number of incidents that have been logged, an average time that takes to resolve the issues and the number of tickets that have been closed. The visual breakdowns according to year, severity, client and type of attack help the business users to see where the incidents are concentrated in and how they change over time. Through the charts, we can be able to see a trend of the critical and high-severity issues, pie and bar charts enable us to see the differences in type of attack malware, phishing, and insider attacks and their contribution to the number of incidents and resolution. Such a top-level survey assists business departments in setting priorities and allocating resources in a better way.

Figure 3.2 – Power BI: Security Audits Dashboard

The dashboard is concerned with the audit aspect of the company known as CyberSec. It provides overview audit counts, average risks score and grouping audits by their severity (high, medium, low). Business users are able to access an overview of risk scoring changes over time and clients which would consistently score high or low in audits. These charts have been structured in a way that identifies risk-intensive clients easily and make informed decisions. The unambiguous design enables even non-technical stakeholders to get a picture of the audit mentalities on different clients and over different periods, which contributed to the accuracy of evaluating organizational preparedness and level of compliance.

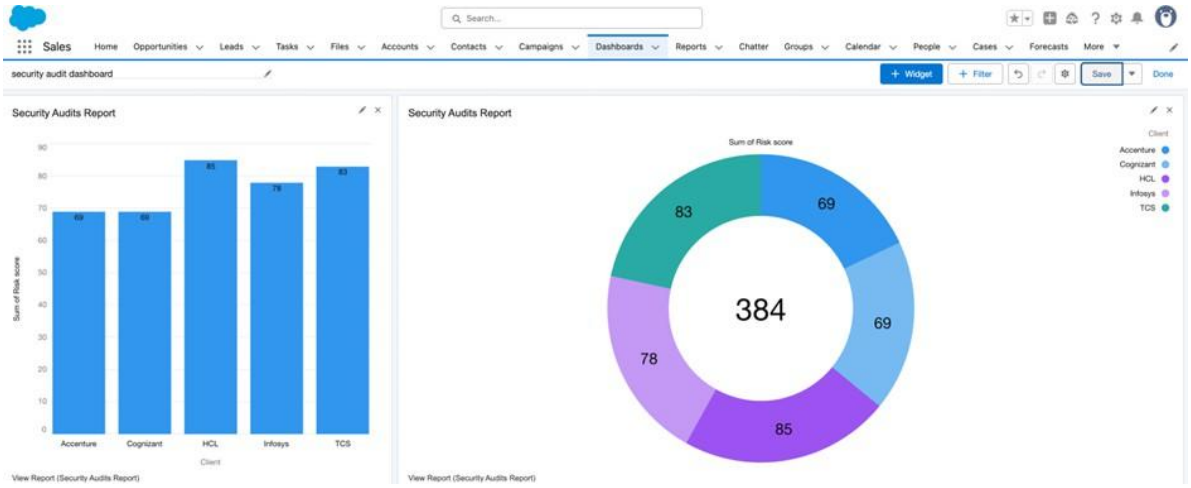

Figure 3.3 Salesforce Dashboards: Audit Views

Salesforce-constructed dashboards will contain the same level of insights but are embedded into the active CRM system. The dashboard version of the incident report looks at the resolution time according to ticket status (e.g. open, investigating, resolved), as well as providing a client-wise summary of all incidents that a team can get a snapshot of any immediate workloads. Audit dashboard enables comparison of the risk scores among the clients and is useful in determining the areas to focus. All the legitimate team members can access these dashboards hence they bring clarity when performing day to day activities as well as during reporting sessions or internal reviews.

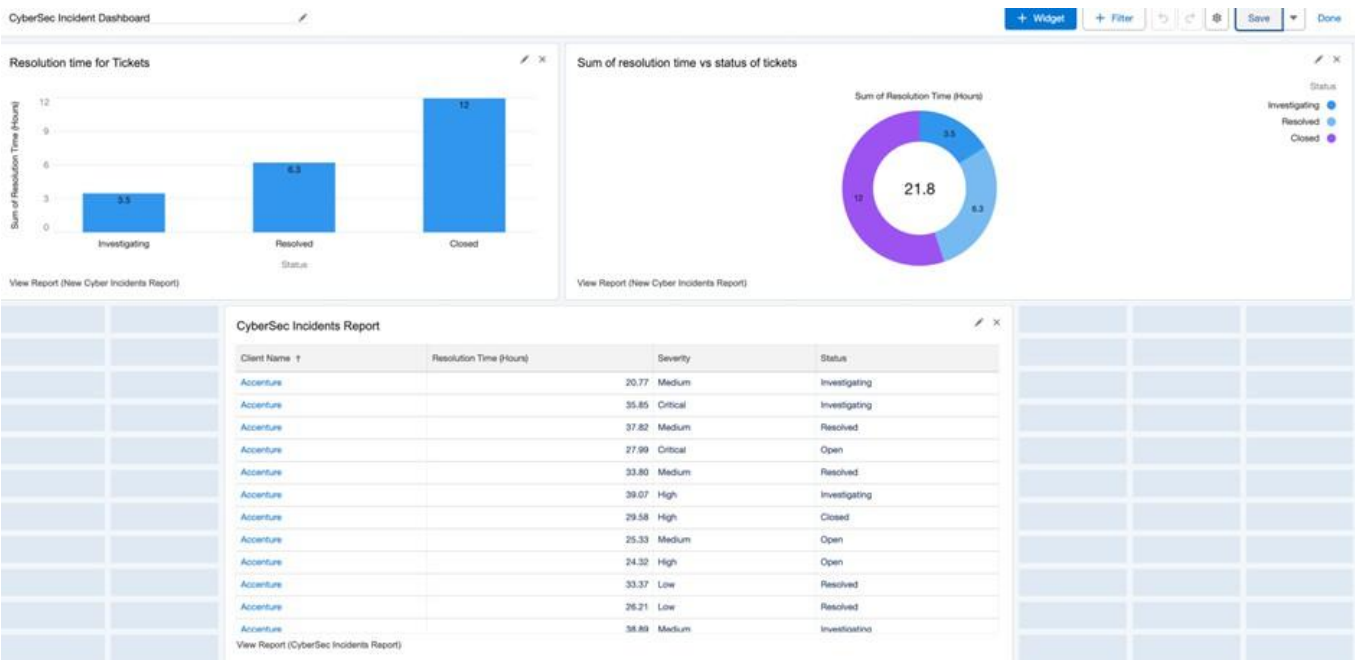

Figure 3.4 Salesforce Dashboard: Incident

These dashboards collectively form the critical component of the business solving solution since they transform confusing records into favorable and easily consumable pictures. They can enable CyberSec teams of varied technical competency to process their data faster helping them to be more efficient in the speed of decision-making and in delivering a more efficient level of service to the client. The dashboards fulfill both the reporting and the improving business alignment objectives of the security activities including increasing transparency of operations by providing macro and micro perspectives of security activities.

4. Initial Business Response & Solution Effectiveness

The post-deployment assessment of the combined Salesforce and Power BI technology at CyberSec indicates a significant increase in the effectiveness of the operations and user experience. Through the integration of previously separated work activities into an all-encompassing CRM selection, employees get convenient access to uniformly available data, have less duplicate sources, and find a more dynamic method of recording, monitoring, and analyzing incidents and audits. This transition has helped not only consultants but also managers gain a clear view of client cases, the assignment of consultants but the instant results of audit activities- which are key problem areas that slowed expansion and traceability within the legacy system.

The shift of manual-based tracking systems, like Excel and email-based coordination, to CRM-based recordkeeping and live dashboards have really boosted response times. Consultants can get ready-made instructions and validate fields that cannot be used to enter inconsistent data, and decision-makers can get immediate information in the form of graphic reports in which they can filter by client, type of attack, and level of severity. More importantly, strategic planning has also become possible since metrics that are not only historical can also be tracked. Measurement and analysis of the consultant productivity and resolution time distribution is a new activity that introduces a change of culture towards accountability and performance correspondence.

Early Indicators of Business Value:

- **Faster Insights**: The new approach allows executives to create incident and audit summaries within a few seconds as opposed to the cumulative hours of data aggregation.
- **Better Traceability**: The data sourced by lookup will provide complete connectivity between records and clients or consultants with live status enabled.
- **Process Standardization**: The standardized process by the homogenous field structures and checking system has reduced significantly errors, besides the variations in input error.

Table: Business Gap Analysis – Before vs After CRM-BI Implementation

Category	Before CRM-BI Deployment	After CRM-BI Deployment
Incident Visibility	Scattered data in local files and shared drives	Centralized dashboards with dynamic filters
Audit Risk Assessment	Subjective, inconsistent scoring methods	Standardized risk fields, visual risk segmentation

Reporting & KPIs	Manual aggregation, slow reporting cycles	Automated visual insights updated in real time
Decision-Making	Fragmented data, intuition-led responses	Data-driven actions with full operational visibility

Table 4.1 Business Gap Analysis – Before vs After CRM-BI Implementation

Although the implementation process is in its initial phase, it can be noted that it has already provided the clear structure, consistency, and clarity in the operations in CyberSec. Team leads are reporting enhanced communication with an accelerated response cycle and the stakeholders are pleased with the high level of visibility through the service lifecycle. The intentionally designed CRM core of the system and its user-friendly BI graphics preparation sets the base to be enriched with capabilities, like automation, advanced analytics, or client self-service portals, and make the organization ready to act strategically on an ongoing basis.

5. Conclusion & Future work

The process of dealing with the CyberSec CRM-BI solution was highly educational in the terms of the multidimensional experience which was gained in the field characterized by interactions with Salesforce CRM customization tasks, BI reporting, data validation, and stakeholder alignment. The practical incorporation of mock data, declarative automation, Apex scripting and power BI dashboards mimicked the issues of a production implementation within an enterprise. This project was not just a construction of a technical solution but more of discovering how structured data system can reinvent service deliveries in industries where stakes are high such as in cybersecurity.

The most problematic aspect of the project was ensuring that all the data was preserved between the relational architecture of Salesforce and the mock data sets, which were external. Problems such as picklist mismatches, look up reference failures, and field level import problems created a lot of challenges at the initial period of data population. It took a lot of technical depth in understanding SOQL queries, Salesforce object metadata, and Apex-based approaches to bulk record insertion and validation to figure out how to overcome these difficulties. This stage was long winded but necessary to realize the importance of clean data structure in establishing scalability of CRM applications.

Reflectively, additional time spent in the design and pre-schema planning and testing early in the process linking accounts and clients would have scripted fewer iterations. It will also be beneficial to engage the dashboards earlier in the cycle, which would have enhanced the consistency of UI/UX design on both Power BI and Salesforce reports. The wider consideration of automation and trigger-driven activity could have built more intelligence into the system, such as automatically assigning consultants depending on whether they had any active cases; i.e. potentially by workload, and turning off alerts in low-risk audit scores. These are lessons which will definitely be of benefit to future projects on multi-modal system designs.

To be further improved, the solution may be supplemented with machine learning, including, but not limited to, anomaly detection in audit risk patterns or prediction of the review time. The integration with Experience Cloud would also enable the clients to trace the progress of their own incident or audit which will lead to transparency. Lastly, it could also be a good idea to enable real-time notifications of a critical incident using Slack or email to make the system more proactive in approaching cybersecurity.

Moreover, team cooperation was mainly effective in order to deliver the project with high quality, on time. The division of roles and responsibilities with each member taking care of creating dashboards, mock data creation, Apex scripting and creating reports ensured that everybody worked according to their strengths. The distributed mode did not only serve well to guarantee coverage in all the sections of documentation written but it also gave an impression similar to that of a real working collaborative type setup. It solidified the significance of effective communication, well-organized task management, and peer-reviews which are also more crucial in any successful IT implementation as the technical proficiency is.

Final Reflections – Key Learnings & Forward Paths

- **Data Quality is Everything**: When it lacks structure and cleanness at scale even the most well-designed CRM dematerialises.
- **Low-Code ≠ No-Code**: The Apex scripting was necessary where the declarative features were not sufficient: data validation, insertion were just a few.
- **Plan the Architecture, Not Just the Interface**: A solid data model avoids time wastage, makes it traceable and drives improved analytics.
- **BI + CRM = Strategic Advantage**: Integration of Power BI and Salesforce created a competitive advantage in terms of monitoring, decision-making and reporting.
